

## THE URBAN/SUBURBAN OPOSSUM

The Opossum is a mammal about the size of a house cat (4 - 14 lbs). It has moderately long fur that ranges in color from white to dark gray and is frequently darker on the legs and lighter on the back. Its face is long and pointed with dark, rounded, paper-thin, hairless ears. Opossums have 50 teeth, more than any other North American mammal, that it readily shows when it is afraid; however showing its teeth is usually the extent of its actions.

Playing "possum" is another defensive mechanism frequently used, but misinterpreted by many that the animal is sick or injured. The tail is hairless, scaly, and prehensile. They have five toes on each foot, and the inside toe on the hind foot is opposable. Opossums have expanded their range to include all of California. The opossum is an animal commonly found in urban areas of the City of Long Beach and Los Angeles County, and generally poses no threat to human or pet populations. However, some people have concerns about the opossums' nightly forages in their yards.

Opossums are the only marsupials (pouched mammals) in North America. They breed from January through November and produce two litters per year. The undeveloped young are born 13 days after mating. They crawl to the female pouch (marsupium) and attach themselves to one of the 7 - 13 teats. Development continues in the pouch for 7 - 8 weeks. Young opossums will stay with the female until they are weaned at about 4 months-of-age. Except for females with young, opossums are solitary animals. Opossums are omnivores and eat a wide variety of foods including fruits, vegetables, nuts, meat, eggs, insects, pet food, and garbage. They are found in many different habitats from woodlands to highly developed residential areas. In urban areas, they have been found living in attics, garages, chimneys, woodpiles, under houses or decks, or in any place that offers protection. Although they are very common in urban areas, opossums are not often seen due to their nocturnal habits.

When opossums live in or near inhabited buildings, the animal's smelly nesting habits and discharge of anal fluids can cause offensive odors. Opossums can damage buildings by pushing in screened vents or window screens, scattering insulation, and chewing electrical wiring. They frequently get into garbage and may injure pets or expose them to disease in disputes over pet food. Opossums also prey on wild birds and baby rattlesnakes.

Opossums are carriers of many diseases: tuberculosis, relapsing fever, herpes virus, tularemia, salmonella, spotted fever, toxoplasmosis, coccidiosis, trichomoniasis, Chagas Disease, yellow fever, and rabies (rarely). They are important reservoirs for leptospirosis (hemorrhagic jaundice) in wildlife and humans. Leptospirosis is transmitted through the urine and feces of infected animals. Humans frequently pick up the disease by eating unwashed produce or windfall fruit or by putting unwashed hands to their mouth (gum, cigarettes, etc.) Opossums are also heavily infested with fleas, ticks, mites, and lice, which are known carriers and transmitters of disease.

Opossums are attracted to urban areas by the easy accessibility of food, water, and shelter. Reducing or eliminating the availability of all of these factors will keep opossums from moving in or encourage them to leave. Tight fitting lids should be kept on garbage cans; pets should be fed during daylight hours and any leftovers removed immediately; water bowls should be emptied or taken in at night; gardens should be frequently harvested and windfall fruit picked up. Food should never be intentionally left out for wild mammals. Opossums can be excluded from buildings by covering foundation vents with slotted metal vent covers and by using 1/4 inch grid screening to cover attic vents and chimneys. Opossums have been known to enter homes through pet doors. Keep pet doors locked at night. Opossums sometimes take up residence under low decks. They may be excluded by using 1/4 inch grid screening or solid metal flashing.

Trench around the perimeter of the deck a minimum of 12 inches deep, insert screening in trench, and backfill. Attach top of screening to facade of deck with nails or fence post staples. Before completing final seal on the last entry point, it is wise to make sure no animals are trapped inside. On the night before completing repairs, sprinkle flour in the entrance hole, and check for tracks the following morning. If no tracks are evident for 3 consecutive nights, no animals are likely present. You may wish to make a temporary screening into a cone or funnel shape. The large end should be sized to encircle the entry hole and be attached to the facade of the deck or building with nails or fence post staples. The small end should face away from the house and be 4 inches in diameter. Opossums can be kept away from roof areas by trimming tree branches 10 feet from roof

and by keeping climbing plants trimmed away from eave areas.

Animal Care Services will respond to and impound any opossum that is:

**Injured/Sick/Dead**

**Has been involved in a bite with a human**

If any of these conditions exist, please call City of Long Beach Animal Care Services at:

**(562) 570-7387**
